Abstract

The Basel III will have a significant impact on the European banking sector. In September 2010, supervisors of various countries adopted the new rules proposed by the prudential Committee on Banking Supervision to be applied to the business of credit institutions (hereinafter called ICs) in a phased manner from 2013, assuming to its full implementation by 2019. The purpose of this new regulation is to limit the excessive risk that these institutions took on the period preceding the global financial crisis of 2008. This new regulation is known in slang by Basel III.

Depending on the requirement of Basel II for banks and their supervisors to assess the soundness and adequacy of internal risk measurement and credit management systems, the development of methodologies for the validation of internal and external evaluation systems is clearly an important issue. More specifically, there is a need to develop tools to validate the systems used to generate the parameters (such as PD, LGD, EAD and ratings of perceived risk) that serve as starting points for the IRB approach for credit risk. In this context, the work is composed of a number of approaches and tools used to evaluate the robustness of these elements IRB systems.

Key words – Credit Risk, Rating, Banking, Renewable Energies
I - Introduction

The Basel Committee, in proposing the method of Internal Ratings Based Approach or IRB, which is based largely on an internal valuation of assets and exposures of the bank, aimed to secure two essential objectives consistent with those supporting the wider review of the New Agreement capital:

1. The use of risk assessment models more sensitive to credit risk, allowing the determination of capital requirements more closely aligned with the potential economic loss that may occur in the bank's assets;
2. Encouraging the use of more advanced models, something that an IRB appropriately structured methodology can provide, motivate banks to continue to improve their internal risk management practices.

One of the most innovative aspects of the New Accord is called the approach or method of internal ratings (or IRB) approach to credit risk and provides two variants, with different degree of complexity: a simplified / basic version or Foundation and an advanced version or Advanced. The first (Foundation) is only determined internally PD (default probability) ¹. In the second (Advanced) are determined four parameters: PD, LGD (loss given default), EAD (exposure at default) and M (mature).

II - Parameters and Variables

The main difference between the two variants is related to the entity responsible for establishing and determining the parameters in question, as we see in the following figure.

---

¹For retail segment is permitted only variant Advanced, thou is, have to be determined internally the four parameters

In Portugal, Banco Espírito Santo (BES) became the first Portuguese financial institution to obtain IRB accreditation of the Bank of Portugal, for the calculation of capital requirements to cover risk crédito.²

The design of a validation methodology of rating analysis depends on the type of classification system, made by the bank. This can vary in several ways, depending on the type of borrower risk, the relevance of exposure, the dynamic properties of the classification methodology, and the availability of standard data and quality ratings of external credit. As a consequence, validation is a relatively complex issue and requires a good understanding of the rating system and its properties.

Most of the validation process focuses on a static point of view, in which the features of an IRB system (calibration, performance) are evaluated for a given set of criteria. This discussion about your design emphasized the need to infer the stochastic behavior of rating transitions within an IRB system. In contrast, the discussion on benchmarking stresses the need to change from an approach that is completely exogenous, in many respects incomplete for a more complete approach in its ideal form would cover a model of equivalence.

²http://Noticias.sapo.pt/lusa/artigo/9628372.html
Broadly the variables to be analyzed can be defined as follows:

- **Probability of Default (PD)** - Probability of default of a given borrower, calculated for a time horizon of one year.
- **Loss Given Default (LGD)** - Measure of expected loss in case of default may be seen up to 100% of the loan amount, depending on the risk mitigation instruments used in their coverage.
- **Exposure at Default (EAD)** - Measure that represents the total exposure value in euro at the time to declare default. Exposure at default is determined for each loan individually considered.
- **Maturity (M)** – Measure of effective maturity of the credit. Maturity is a weighted measure of the life of the loan, ie, the percentage of equity paid in each year weighted by year to which it relates.

In the analysis of the parameter estimates of PD, LGD and EAD model can distinguish two approaches, backtesting and benchmarking.

- Backtesting means using statistical methods to compare the estimations of the three components mentioned above. Whereas, for the risk models backtesting market involves the whole model is, by internal rating systems only risk components (model inputs) are tested and the "model" is provided by the supervisor, regarding the form of the functions risk weighting.

- Benchmarking refers to a comparison of internal estimates between banks and / or external benchmarks (eg external ratings or models developed by supervisors).

The **PD** should be calculated taking into account its historical, associated with the credit quality of the borrower data. This quality score is given by (rating) assigned by the internal model. The most popular application of this technique is empirical, with the **PD**
relatively to each class of risk to be determined from the historical frequency of defaults recorded by the debtors of this class, using enough to cover good and bad years of economic performance period. Compiling records of various annual fees, the average historical rates, which provides a long-term rate can be calculated. One of the reasons why there is a wide enough period for the IRB Advanced is 5 years and the IRB Foundation starts with two years, this period should increase each year until data covering at least 5 years, is that a reference to a single year can contain exceptional elements and may not reflect the average actual default.

Highlight that to exist defaults must be one of the following conditions (Notice of Banco de Portugal No 5/2007):

a) The Institution assign a low probability to the possibility that the borrower will comply fully with their obligations to the institution itself, or any of its subsidiaries, parent company not resort to measures such as the execution of any warranty;

b) The Institution considers likely to have to meet the obligations of the counterparty, and their recovery is doubtful in the case of off-balance sheet;

c) The debtor register a delay exceeding 90 days (this is the most common situation) for a significant obligation to the institution, its subsidiaries or any of its parent company. The 90 day period may be extended to 180 days in the case of exposures to public sector entities (such as regional and local authorities). On the other hand, in the case of significant discovered, the delay should be counted at the time the obligor has breached an advised limit, has been advised of the set a lower threshold current outstandings, or has drawn, in an unauthorized manner, credit amounts. In the case of credit cards, the delay should start being counted from the date of the minimum payment.

LGD configures the severity of the failure, this menas, the expected loss is a credit transaction, the counterparty will default. The complement is the recovery rate. LGD is usually calculated as a percentage of the EAD, this percentage may be obtained at time
of failure for cases already in default or correspond to an estimated loss conditional upon
default, for cases where there is no default, which is the majority.

In calculating the estimated LGD beyond the level of recovery, there is a need to
consider the amount and type of side or operation when it exists. The recoveries may
materialize in cash or through the appropriation of property, the latter type of recovery
but generating an exposure to market risk (discount or haircuts), when it is attempted to
convert them into monetary values.

LGD is calculated, taking into consideration the amount of recovery (R), the direct and
indirect administrative (C) cost recovery and appropriate discount rate (i) to discount to
present the expected flows of receipts and payments that should incorporate the risk-free
rate (associated with government bonds) plus a spread showing the risk of default and
(t) corresponding to the timeframe in which there are monetary flows. The formula is as
follows:

\[
LGD = 1 - \frac{\sum_{t=1}^{n} \frac{R_t}{(1+i)^t} - \sum_{t=1}^{n} \frac{C_t}{(1+i)^t}}{EAD}
\]

The EAD is a measure that represents the total exposure value, in euro at the time to
declare default. Exposure at default is determined for each loan individually considered.
It should be borne in mind that this exhibition enter the off-balance sheet items (in case
of unused credit lines - potential liabilities recorded off balance sheet) for which should
be used conversion factors TLC (credit conversion factors). For example for a line of
credit with a maturity more than 1 year, a factor of 50% should be used. Thus, the
current EAD = Exposure x + CCF (part unused credit limit).
The Maturity (M) is a measure of the effective maturity of the credit. The maturity is a weighted average life of the loan, that means, the percentage of equity paid in each year weighted by year to which it relates. For example, a loan to two years of 200, 100 payable in each year, the maturity will equal: \[ M = (1 \times \frac{100}{200}) + (2 \times \frac{100}{200}) = 1.5 \] years. In the IRB approach Foundation in credit to companies (corporate) will use a mature standard, set in New Agreement of 2.5 years.

III - Rating

Banks must document its evaluation criteria and provide appropriate follow-up when given class differs from the assessment indicated by test to be applied. The requirements are defined for:

- promote consistent application of the criteria \textit{rating};
- assess credit conservatively when there is greater uncertainty;
- understand the financial condition of the Borrower over the coming period;
- use of models \textit{rating} com and comprehensive statistical power of all significant variables.

The Bank must demonstrate that their criterion covers all the factors that are relevant to risk analysis of the borrower. Factors must demonstrate the ability to differentiate risk, anticipate events, have discriminative power, be relevant and intuitive to ensure that the \textit{ratings} are designed to distinguish the risk, and not to minimize capital requirements.

The first \textit{input} for the IRB approach is the calculation of the Bank for each of its internal rating grades. Borrowers as without risk to defaulting borrowers, the \textbf{PD} calculate for each level can vary by many orders of magnitude, thus making this a highly sensitive measure of risk.

For each level of its internal rating, the Bank calculates a probability of default for one year.
Banks should consider all available information to calculate PD using the following three techniques for calculation:

- experience of internal failure;
- association of external data;
- statistical models of default.

How many more are the techniques and data sources used by a bank, the greater the confidence in their own calculations PD.

Accordingly the BIS (Bank of International Settlements), it follows that also that a system Rating will also have the following additional functions:

- Authorities approved credit limits;
- Review of lending rates;
- Informe the risk profile of the Bank's portfolio and the Directors to Board Directorate;
- Analysis of the adequacy of the Bank's capital reserves and profitability;
- Performance under pressure tests to assess capital adequacy.

IV - Electricity from renewable energies in Portugal

Portugal in gross electricity consumption in 2008 was recognized as the fifth country in the European Union with greater integration of renewable energy, however it is also the fifth country with energy dependence in the European Union. This dependence led to the development of ways to minimized, yielding strong investment in the sector. Recent statistics published by the General Directorate of Energy and Geology, reveal that in October 2010 Portugal enjoyed 9405 MW of capacity to generate electricity from them.

The strategy implemented in this sector is a growth strategy or development. Defined based on various constraints, involves intervention of other entities, influences before the final consumer, eliminating bureaucracy and the development of specific competencies (Pereira, 1998). To implement quality and accreditation in order to guarantee and ensure the viability of the system, the existence of professional skills and the promotion of research and development is required. The expected result is the implementation of
sustainable economic growth (Velasco, 2009), contributing to the elimination of harmful effects to the environment, preserving the reserve of energy in the world, create jobs (Perez, 2001) and can generate a surplus of energy reserves allowing foster exports and will not need to import so many features and consequently contribute to the equilibrium of the balance of payments.

V – Study of Portuguese renewable energy companies

On this part of the article we tried to study the risk of a group of 30 Portuguese companies.

We considered a dependent variable that is the amount of money that the companies must pay to the State divided by the total assets from the company.

Note that we consider this variable as a proxy to the credit risk. We should use a variable related to the credit banking but this type of information is not available. So we use a proxy variable working the amount of money that should be payable to the fiscal administration.

As independent variables we use financial autonomy, solvability, Debt to Equity ratio, Liquidity, Cash Flow, Sales evolution, ROE (return on Equity), Receivable time, payable time, debt long term.

This Model has a coefficient of adjustment of almost 46% as below.

<table>
<thead>

</table>

a. Predictors: (Constant), Empréstimos Obtidos mp, Autonomia Financeira, Prazo médio fornecedores, Debt to Equity, Prazo médio receb / pag., Evolução Vendas, Solvabilidade, Roi, Cflow, Liquidade

b. Dependent Variable: Estado/Ativo

About the variables we get the following results after applying a linear model
From this results we conclude that only solvability, cash flow, sales evolution and debt on long term are statistical relevant.

We repeated the first step for the model but we get R square lower than the first one.

Conclusion

A bank must demonstrate to its supervisor capabilities before adopting the IRB Approach on a continuous basis. The data collection requirements are closely aligned with the capacity of banks to validate their calculations PD and models rating

The Committee recognizes that the fundamental choice of a model approach under the IRB capital requirements should be based on the nature of their holdings and the adequacy of the same underlying methodologies. As an example, when bank profits are
materially affected by market volatility of their equity positions, the approach should try to capture this risk.

Relatively to the work methodologies, Benchmarking is an important part of the validation process and, in many cases, appears as an important empirical complement to the more rigorous and formal approach. However, benchmarking remains in many cases as subjective and need to be more formal.

Relatively to the supervision of this evaluation can then focus on evaluating the quality of work systems.

From the study of the Portuguese companies in the renewable sector, we get problems on getting a good pack of variables that could explain the risk from the companies. One alternative was to divide the companies in company insolvent and solvent.
